PORTALDOT HACKER HOUSE 2026 · ECOSYSTEM DAPPS

Portion

Share what an asset earns, with a record everyone can check.

Live testnet app: portion-one.vercel.app · Code: github.com/Nailer/portion

Team: Sukuna (solo builder) · Test network and test tokens only. Test tokens have no value.

THE PROBLEM

Sharing equipment income still runs on trust

The operator

Runs solar panels, vehicles or machinery, and reports deposits and works out each backer’s split by hand.

The backers

See emailed statements and bank transfers, so they take the numbers on the operator’s word.

Both sides

Have no shared record of the terms, what was paid in, or who is owed what.

HOW SURE ARE WE?

This is our working assumption, not a finding.

No operator has been interviewed yet. Testing how much this costs them, and whether they would pay to fix it, is the first milestone.

THE PRODUCT

One record, from agreed terms to each payout

1

Publish

The operator sets out hashed terms, a share count, a deposit schedule and a bond.

2

Fund

Backers read the terms and risks, buy shares, and stake them to earn.

3

Deposit

The operator pays in revenue. After a 0.5% fee, it is split by staked shares.

4

Claim

Each holder claims their own part, and every step is a public transaction.

Portion doesn’t create revenue or guarantee returns. Holders receive only money the operator actually deposits.

WHY PORTALDOT

Portion depends on V3’s native modules and EVM working as one

One signature. All steps succeed or none do.

Deed	Terms hash	Shares	Allowances	Solidity sale
`Nfts.mint`	`Nfts.setAttribute`	`NftFractionalization`	`Assets.approve ×2`	`Revive.call → create`

Native assets in Solidity

Shares and test pUSD reach the contract as ordinary ERC-20 tokens through precompiles, so no token contracts are needed.

Deed tied to supply

Fractionalization locks the deed against a fixed share supply, and the app checks that link from the chain.

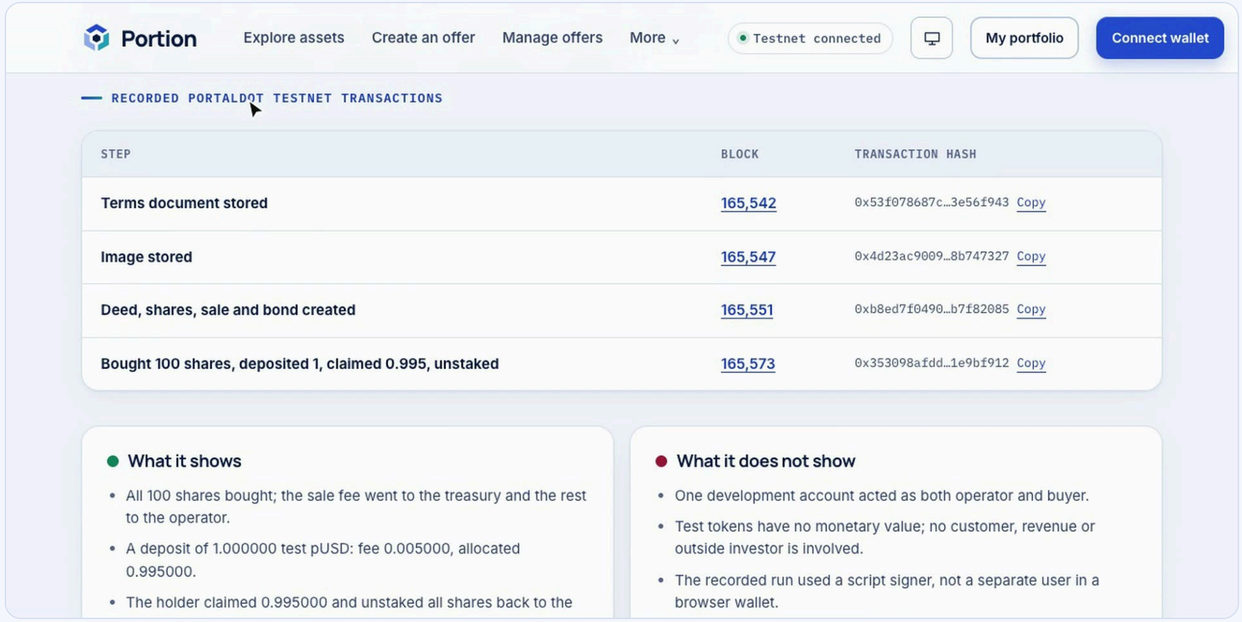

Terms kept by the chain

TransactionStorage holds the documents, and their hash sits on the deed, so anyone can compare the bytes.

A plain database could run the admin. Portaldot matters when backers must check the record themselves.

LIVE PORTALDOT TESTNET

The contract is live, and the full cycle has run

Create → buy → deposit → claim

Finalized on chain. 1 test pUSD deposited, 0.995 claimed after the 0.5% fee.

337 automated tests

Contracts, SDK, web and server, passing in CI, across 80+ commits since 16 Oct.

The limit

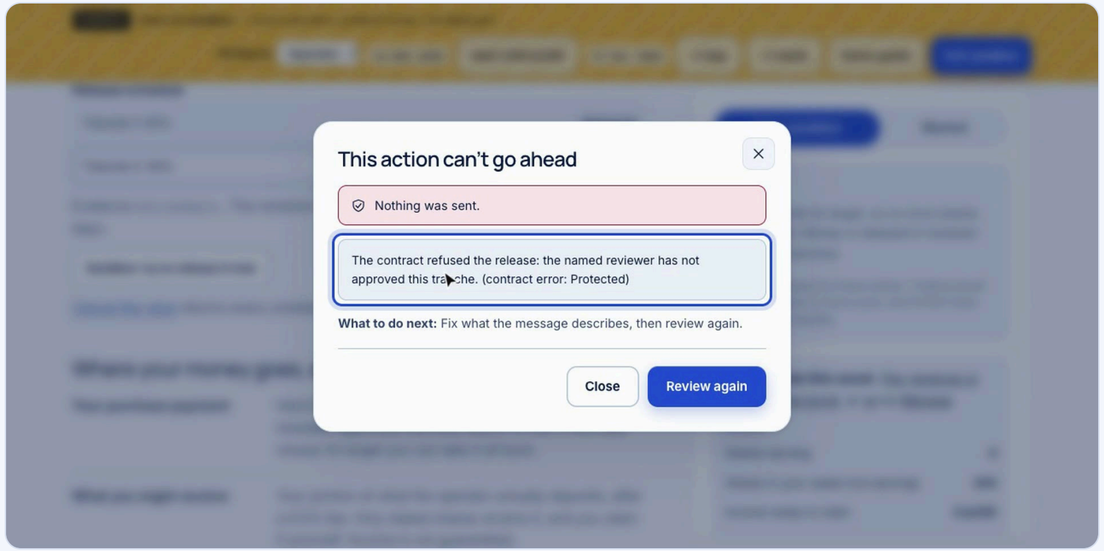

One development account played both roles, signed by a script. No separate users yet.

`Core contract 0x17501f4510ba4298b618209e105cd47036509706 (block 160,455)`

`Deploy tx 0x6bdc10ea83152665dc6d7007d217ee4648af6fe0d6efd7b3f4f6697911034b70`

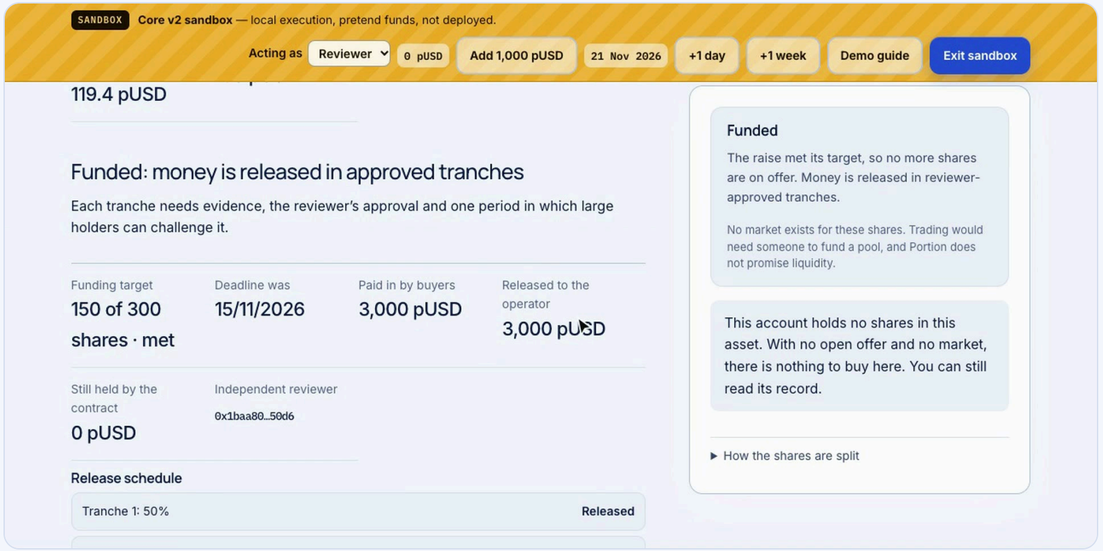

BROWSER SANDBOX · NOT ON PORTALDOT

Core v2 holds the money until a reviewer approves

The operator tries to release: refused

The refusal comes from the contract itself, not from the page.

Reviewer approves, the window passes: released

The one-week challenge window is a simulated time skip.

Core v2 bytecode in a browser EVM, with pretend funds and fictional roles. Not deployed, not audited.

WHAT WE FOUND AND FIXED

Our own review found loopholes; Core v2 closes or narrows them

Question	Core v1 · live on testnet	Core v2 · sandbox only
Purchase money	Paid straight to the operator, less 1%	Held by the contract and released in tranches
Opening a sale	Anyone can list	A named reviewer must attest on chain first
Target missed	No minimum raise	Every buyer is refunded in full
Operator fails	Recovery limited to the bond (at least 5%)	Unreleased money is also refunded pro rata
Emergency	No pause	Pause of at most 7 days; claims and refunds keep working

Core v2 is not deployed or audited. Deploying it needs about 800–1,110 tPOT of storage deposit.

WHAT IS NOT PROTECTED

Software can enforce the split, but not the truth of the income

The live contract enforces

- Offered shares and a bond are held by the contract
- Deposits are split by stake, with the fee shown
- Only the holder can claim
- New purchases stop in default

It relies on people for

- The equipment existing, and the right to use it
- Depositing what was truly earned
- Spending purchase money as described
- Someone submitting a slash

Not provided yet

- Escrow on the live contract
- Independent asset or revenue checks
- Protection of principal
- A market for shares, or automatic payouts
- An audit or a legal opinion

THE MARKET

Working models control the asset, the money or a legal wrapper

Alternative	How it works today
Sun Exchange, Energea	Run the assets or the offerings themselves, and pay owners on a schedule
Centrifuge	Tokenizes assets through a legal vehicle and draws on-chain financing
Juniper Square	Sells reporting and fund administration software to the sponsor
Spreadsheets	Free and familiar, but with no shared record

Our narrower bet

A checkable payout record for small operators who already have backers. Sponsor-side software is the closest model. Whether it beats a spreadsheet is untested.

THE BUSINESS MODEL

Fees alone don’t pay for the work, so we propose a subscription

$240,000

deposited per year by one operator, just for the 0.5% fee to cover serving them

105

operators needed at $300 a month to cover a $250,000-a-year team

24

operators needed at $1,000 a month to cover the same team

No customer, pilot or price has been agreed

These are modelled assumptions. Contract fees (1% of sales, 0.5% of deposits) are charged only in test tokens today.

Assumes $400 onboarding and $100 a month to serve an operator. Reproduce: node scripts/financial-model.mjs · 10

WHY KEEP SUPPORTING THIS

Support tied to evidence, one milestone at a time

What comes next, in order

1. Discovery with a real solar operator, recorded as said
2. A one-page pilot scope with a stated price
3. A separate user signs in a browser wallet, with receipts
4. Core v2 on testnet, then an external review
5. Named reviewers and a legal view before any real money

What would end it

No operator pain, no willingness to pay, or a legal blocker in the first market.

What Portaldot gains

An MIT-licensed worked example and SDK for using native assets from Solidity, and an RWA app whose deposits and claims recur if operators adopt it.

What we ask for

Technical review of Core v2, test tokens for its deployment and separate-user tests, and later, mainnet migration guidance.

Where Portion stands today

LIVE TESTNET

Core v1 deployed, with a finalized create, buy, deposit and claim cycle from one development account.

SANDBOX

Core v2 escrow, reviewers and refunds, running locally in the browser with pretend funds.

FUTURE

A paid operator service, a real pilot and an audit. There are no customers yet.

App: portion-one.vercel.app · Sandbox: portion-one.vercel.app/sandbox

Evidence: portion-one.vercel.app/evidence · Code: github.com/Nailer/portion

Everything here is on a test network or labelled as a sandbox, and we have said what it doesn’t protect. Next, we test it with a real operator.
